

-Before I start the video demo let me explain whats going on here

-On the right side is me in the ec2 instance via SSM

-On the left is the cloudwatch metric showing CPU utilization of the ec2 instance

-Its a bit blurry to see but on the left you can see theres one ec2 instance running currently. That will change soon after a few minutes of simulating CPU usage on the current ec2 instance via stress - - cpu 2

AFTER 4 MINUTE MARK

-As you can see on the left, the cpu usage on the ec2 instance has skyrocketed and is at 78% utilization

-A new ec2 instance should be created by the autoscaling group any moment now

AFTER 1 MINUTE

-As you can see, a new ec2 instance has been launched and is up and running. It uses the same template as the previous ec2 instance, meaning I can ssm into it the exact same way and it has the exact same permissions

ON AUTO-SCALING-GROUP

And as you can see here on the Activity logs of the Auto-Scaling Group, it launched an ec2 instance automatically when the cpu usage spiked.

After I stopped the stress test, you can see that the Auto-Scaling Group terminated the ec2 instance it launched and you can see on the ec2 instances section it was terminated.
